VITAL STATISTICS
OF
NEW YORK STATE
1978

New York State Department of Health

David Axelrod, M.D., Commissioner

FOREWORD

This report of the Office of Biostatistics summarizes selected vital and health statistics for the resident population of the State for the year 1978. It presents representative data reflecting the needs and interests of consumers of health information.

These statistics provide a useful, quantitative data base for consumers in the public and private sectors in support of a variety of uses and activities — population dynamics, health economics, planning, program development and evaluation, research, surveillance.

David Axelrod, M.D.
Commissioner of Health

Vital Statistics of New York State

INTRODUCTION

This report is a summary of selected 1978 vital and health statistics for New York State. The information presented is compiled from the automated vital and health statistics information system of the Office of Biostatistics, New York State Department of Health. The major sources of data are certificates of live birth, death, fetal death, marriage and dissolution of marriage, the federal census and related federal and state information reporting systems. Records of vital events occurring in 1978 received by the New York State Department of Health after March 31, 1979 are not included in this report. With the exception of vital events to New York State residents occurring outside of New York State, the number of records excluded is negligible.

This is the ninety-ninth annual report prepared by the Office of Biostatistics. The Office of Biostatistics has also produced a quarterly publication of similar content since 1971. A series of special reports based on vital statistics have appeared in these quarterly and annual publications. A list of the titles and authors that have appeared in this series may be found at the end of this report.

Single copies of the current report are available without charge as long as the supply lasts. Copies of earlier annual reports are still available, however, the supply of reports prior to 1975 is limited. Copies of the quarterly publications are also available. Inquiries should be addressed to the Office of Biostatistics, New York State Department of Health.

HIGHLIGHTS

Population

New York State's July 1, 1978 estimated population was 17,878,900. The New York State population was comprised of an estimated 7,206,000 New York City residents and an estimated 10,672,900 residents in Upstate New York (New York State exclusive of New York City).

The 1978 estimate, 0.3 percent below the 1977 estimated population, was the result of a natural increase of 67,145 and an estimated net loss due to migration of 112,245. The estimated 17,878,900 residents reflected a two percent population decrease in New York State since the 1970 census.

Females constituted approximately 53 percent of New York State's population, males 47 percent.

Half of the State's population was 30 years old or less, nearly a third (31 percent) was under 20 years of age. Approximately 12 percent of the State's population was sixty-five years of age or older.

Twenty-three percent of New York State's estimated 1978 population were females of child bearing age (15 to 44 years).

Live Births

New York State residents gave birth to 233,328 infants during 1978, resulting in a live birth rate of 13.1 live births per 1,000 population. There were 6,434 fewer live births during 1978 than during 1977 with the live birth rate 2.2 percent lower than the 13.4 live births per 1,000 population reported in 1977. Following an unexpected rise in the live birth rate during 1977, the 1978 New York State resident live birth rate returned to the level prevailing from 1973 to 1976. The live birth rate for residents of New York State has averaged 13.1 live births per 1,000 population annually since 1973 with little variation from year to year. The lone exception was 1977.

The general fertility rate among New York State residents was 56.1 live births per 1,000 females aged 15-44 years in 1978, the lowest general fertility rate reported in New York State since 1939 when the general fertility rate was 54.7. The general fertility rate for residents declined steadily from 1970 to 1976, decreasing from 82.5 to 57.3 live births per 1,000 females aged 15-44 years. Coinciding with the increase in the live birth rate, the general fertility rate increased in 1977 to 58.2 live births per 1,000 females aged 15-44 years.

White live births outnumbered nonwhite live births 3.3 to 1 among residents of New York State during 1978. There were 178,158 white births reported and 53,469 nonwhite live births. Both figures were below the corresponding 1977 figures. White live births decreased 3.3 percent in 1978 while nonwhite live births were 2.6 percent lower.

More males then females were born during 1978. Fifty-one percent of all live births to New York State residents were male; forty-nine percent were female. For every 1,000 females born during 1978, 1,054 males were born. Among white infants the ratio was 1,058 males for every 1,000 females and among nonwhites the ratio was 1,040 males per 1,000 females.

The proportion of infants who were premature, i.e., weighed less than 2,501 grams at birth, decreased slightly during 1978. Premature infants comprised 7.7 percent of all New York State resident live births in 1978, 7.8 percent in 1977. The decrease is the result of a decline among only white infants. The proportion of premature white infants decreased from 6.5 percent in 1977 to 6.3 percent in 1978 while the proportion of premature nonwhite infants remained the same in 1978. 12.3 percent.

The highest proportions of premature live births were among mothers aged 45 years or more (14.4 percent) and mothers less than 15 years of age (13.8 percent). Mothers in the 30-34 years and the 25-29 years age groups delivered the lowest proportions of premature live births, 6.5 percent and 6.6 percent, respectively.

The median age of New York State residents who gave birth during 1978 was 26.2 years. Mothers of nonwhite infants were generally younger than the mothers of white infants. The median maternal age for nonwhites was 24.7 years compared to a median maternal age for whites of 26.5 years.

One of every eight live births delivered in 1978 was delivered to a teenage mother. Females less than 20 years of age accounted for 12.4 percent of all live births to New York State residents in 1978. A disproportionate number of these live births to teenagers was nonwhite. Nearly 40 percent of the live births to teenagers were nonwhite, while less than 25 percent of total live births were nonwhite. Teenagers gave birth to 20.6 percent of all nonwhite live births and 9.9 percent of all white live births.

Women in the 25-29 years age group accounted for one-third of all live births reported in 1978, the largest proportion for any age group. Among whites, mothers aged 25-29 years were responsible for the largest proportion of live births (35.4 percent), however, among nonwhites the largest proportion was attributed to women 20-24 years of age.

New York State Public Health Law prohibits the statement on the birth certificate of the marital status of the mother. Data reflecting marital status are estimates inferred by examining statistical information from the birth certificate. The procedure employed is described in "Technical Notes."

An estimated 52,908 live births occurred out-of-wedlock in New York State during 1978. These births represented 22.7 percent of all resident live births during 1978. The proportion of out-of-wedlock live births was highest among mothers under 20 years of age. Out-of-wedlock live births comprised 96.4 percent of the live births to mothers under 15 years of age, 76.4 percent of the live births to mothers 15-17 years of age and 53.3 percent of the live births to mothers 18-19 years of age. The lowest proportion of live births that occurred out-of-wedlock were reported in the 30-34 year age group, 11.0 percent.

First live births which numbered 99,177 constituted 42.5 percent of all live births, second live births 31.4 percent, third live births 15.2 percent and live births of order four or higher 10.9 percent. The distribution of 1978 live births by birth order was essentially the same for whites and nonwhites.

Early prenatal care, i.e, prenatal care during the first trimester of pregnancy, was obtained by 64.7 percent of all residents who gave birth in 1978. No prenatal care was reported for 4.3 percent of all 1978 live births. There was considerable disparity between whites and nonwhites with regard to when prenatal care began. More white mothers obtained prenatal care than nonwhite mothers and they began prenatal care earlier. Early prenatal care was obtained by 72.1 percent of white mothers but only 40.4 percent of nonwhite mothers. Only 2.6 percent of the white mothers reported receiving no prenatal care, in contrast to 9.9 percent of the nonwhite mothers.

Fetal Mortality

New York State Public Health Law requires the registration of all spontaneous fetal deaths regardless of the gestation of the fetus. Unlike birth and death registration, the registration of spontaneous fetal mortality is not uniform across the United States. In order to provide comparable data this report presents data for spontaneous fetal deaths of 20 weeks gestation or more.

In 1978, 2,414 pregnancies of gestation 20 weeks or more ended with a spontaneous fetal death. Among New York State residents there were 10.2 spontaneous fetal deaths of gestation 20 weeks or more for every 1,000 live births plus spontaneous fetal deaths of gestation 20 weeks or more. The rate was highest among the oldest mothers. For women 35-39 years of age 14.7 spontaneous fetal deaths were reported for every 1,000 live births and spontaneous fetal deaths; for women 40-44 years of age the rate was 25.6 and for women 45 years of age or older the rate was 20.2. The lowest rate was reported for women 20-24 years of age, 9.2 spontaneous fetal deaths of gestation 20 weeks or more per 1,000 live births and spontaneous fetal deaths of gestation 20 weeks or more.

The number of induced terminations of pregnancy performed in New York State increased in 1978. A total of 153,704 induced terminations of pregnancy were recorded in the State during 1978, an increase of 4.1 percent above the 147,655 induced terminations of pregnancy recorded in 1977. The number of induced terminations of pregnancy recorded in the State in 1978 was the largest reported since 1974 when more than 161,000 were reported.

More than 90 percent of the induced terminations of pregnancy recorded in New York State were performed for New York State residents. Residents obtained 139,148 induced terminations of pregnancy in the State during 1978, a rate of 33.4 induced terminations of pregnancy were performed at a pace equivalent to one induced termination of pregnancy for every 1.7 live births.

There were more induced terminations of pregnancy than live births reported for two age groups: females under 15 years of age and females over 44 years of age. The ratio of induced terminations of pregnancy per 1,000 live births was 2,494.8 for women over 44 years of age and 2,034.4 for females under 15 years of age. Women 25-29 years of age produced the lowest ratio, 382.4 induced terminations of pregnancy per 1,000 live births.

Detailed characteristics associated with induced terminations of pregnancy recorded in New York State during 1978 will be available soon in the publication "Report of Selected Characteristics of Induced Terminations of Pregnancy Recorded in New York State, 1978".

Mortality

The 1978 crude death rate for residents of New York State was 9.3 deaths per 1,000 population. The rate equalled the crude death rates of 1975 and 1977 as the lowest ever reported in New York State. The number of residents who died in 1978 actually decreased slightly to 166,183. The age-sex adjusted death rate for State residents reached 6.4 deaths per 1,000 population, a new low.

The crude death rate for males decreased from 10.4 deaths per 1,000 males in 1977 to 10.3 deaths per 1,000 males in 1978. The crude death rate for females remained the same in 1977 and 1978, 8.4 deaths per 1,000 females. There were no increases from 1977 to 1978 in the age-sex specific death rates. Males continued to experience higher mortality rates than females in every age group.

In contrast to the mortality pattern for New York State residents in general, mortality among New York State's nonwhite residents increased. There were 19,071 nonwhite resident deaths in 1978, an increase of 4.5 percent from 1977. Nonwhite resident deaths comprised 11.5 percent of all New York State resident deaths in 1978, while they comprised only 10.9 percent in 1976 and 1977.

The five leading causes of death in New York State remained the same as in 1977. These were diseases of the heart, malignant neoplasms, cerebrovascular disease, pneumonia and accidents, which together accounted for 77.9 percent of all deaths. The rate and number of deaths due to the five leading causes of death changed only slightly from 1977 to 1978. Deaths due to heart disease, malignant neoplasms and cerebrovascular disease decreased while deaths due to pneumonia and accidents increased.

Heart disease deaths declined 0.5 percent to 69,398 deaths in 1978. There were 388.2 deaths due to heart disease per 100,000 population among residents of New York State. Among the more specific cause categories that comprise the general category, heart disease, the two principal components, acute myocardial infarction (ICDA 410) and other ischemic heart disease (ICDA 411-414) decreased in 1978. The death rate due to acute myocardial infarction was 151.6 deaths per 100,000 population and the death rate due to other ischemic heart disease was 208.2 deaths per 100,000 population. Heart disease deaths accounted for 41.8 percent of all New York State resident deaths.

Malignant neoplasms caused the death of 36,618 New York State residents in 1978, 0.6 percent fewer than in 1977. The resultant death rate due to malignant neoplasms was 204.8 deaths per 100,000 population. The digestive organs and peritoneum (62.1 deaths per 100,000 population), the respiratory system (47.7), the genital organs (22.2) and the breast (20.8) were the leading sites of fatal malignant neoplasms. Deaths due to malignant neoplasms accounted for 22.0 percent of all New York State resident deaths in 1978.

The largest decrease among the leading causes of death occurred in the number of deaths due to cerebrovascular disease. Cerebrovascular disease deaths decreased 4.0 percent in 1978 to 12,299 deaths. The New York State resident death rate due to cerebrovascular disease was 68.8 deaths per 100,000 population, the third highest cause specific death rate reported. Cerebrovascular disease accounted for 7.4 percent of all New York State resident deaths.

Deaths due to accidents and deaths due to pneumonia were the fourth and fifth leading causes of death among New York State residents in 1978. Each cause accounted for 3.4 percent of all New York State resident deaths. Pneumonia was the cause of 5,647 deaths, an increase of 5.9 percent from 1977. The death rate due to pneumonia was 31.6 deaths per 100,000 population. Deaths due to accidents occurred at a rate of 31.1 deaths per 100,000 population. The number of deaths due to accidents increased 0.9 percent to 5,568 deaths. Nearly half of all accidental deaths were the result of motor vehicle accidents, accounting for 2,569 resident deaths.

Although heart disease, malignant neoplasms, cerebrovascular disease, pneumonia and accidents were the five leading causes of death for the New York State population in general, when age and race were considered, the leading causes of death varied significantly. The leading cause of death among residents between the ages of 1 and 24 years was accidents; malignant neoplasms was the leading cause of death for residents aged 25-44 years and diseases of the heart the leading cause of death for residents 45 years of age and older. The other leading causes of death among the younger element of the population reflected problems in socialization. For example, homicide was one of the five leading causes of death for all age groups between 1 and 44 years of age.

Homicide ranked second for residents 20-24 years of age, third among residents 5-19 years of age and fourth among residents 1-4 years and 25-44 years of age. Suicide ranked third for residents 20-24 years old and fourth for residents 5-19 years old. Cirrhosis of the liver was the third leading cause of death for residents 45-64 years old and fifth among 25-44 year olds. Among the more elderly portion of the population physical problems replaced social problems as the leading causes of death.

Diseases of the heart, malignant neoplasms and cerebrovascular disease were also the leading causes of death among New York State's nonwhite residents; however, cirrhosis of the liver and homicide were the fourth and fifth leading causes of death. Although the rank varied, the leading causes of death for nonwhites by age were essentially the same as those of the general population.

Infant Mortality

Infant mortality among New York State residents continued to decline in 1978. The number of infant deaths reported for residents and the infant death rate per 1,000 live births both reached new lows for the State. There were 3,248 infant deaths in 1978, 5.3 percent fewer than in 1977. The infant death rate declined to 13.9 infant deaths per 1,000 live births.

Neonatal death, death under 28 days of age, comprised 72.0 percent of all infant deaths. The neonatal death rate for New York State residents was 10.0 deaths per 1,000 live births, based on 2,338 neonatal deaths. More than half (57.1 percent) of all neonatal deaths occurred during the first day of life.

The leading causes of death among infants were congenital anomalies (19.1 percent of all infant deaths) and immaturity unqualified (13.9 percent of all infant deaths).

The infant death rate for nonwhites decreased slightly from 1977 to 1978; however, it remained substantially higher than the infant death rate for whites. The infant death rate for nonwhites was 21.0 deaths per 1,000 live births in 1978. Neonatal deaths among nonwhites occurred at a rate of 14.2 deaths per 1,000 live births. The leading causes of infant deaths among nonwhites were immaturity unqualified (17.7 percent) and congenital anomalies (12.6 percent).

Marriages

The number of marriages occurring in New York State increased 2.4 percent during 1978 to 138,447 marriages. Based on data from marriages recorded in Upstate New York, the median age for 1978 brides was 22.3 years and for grooms 24.5 years.

Dissolutions of Marriage

In 1978, 58,043 marriages were dissolved in New York State. This was an increase of 4.0 percent from 1977. The median duration of marriages dissolved in 1978 was 7.3 years.

Figures, Maps and Tables

Detailed vital statistics data presented in tables, figures and maps follow. The tables and charts were designed to provide a data resource and to identify the type of data available. Requests for data not contained in this publication should be addressed to the Director of Health Statistics, Office of Biostatistics. The request should specify the type of data needed and a brief description of the intended use of these data.

TECHNICAL NOTES

Registration

New York State is divided into two Registration Areas, New York City and Upstate New York (New York State exclusive of New York City). New York City is comprised of the five counties of Bronx, Kings (Brooklyn), Queens, New York (Manhattan) and Richmond; the remaining 57 counties comprise Upstate New York.

It is possible to publish summary vital statistics for total New York State through a cooperative exchange of data between the two Registration Areas. The Office of Biostatistics of the New York State Department of Health processes data from live birth, death and fetal death certificates recorded in Upstate New York and through a cooperative arrangement tabulates data on live births, deaths and fetal deaths recorded in New York City and on live births and deaths recorded out of State but in the United States or Canada.

Residence

Unless otherwise specified in the titles of the tables, the vital statistics presented in this report are based on the vital records of events to New York State residents occurring in the United States and Canada. The events are allocated to the place of usual residence as reported on the certificates with the following exception. Vital events occurring to inmates of state and federal institutions are allocated to their residence at the time of admission. Vital events occurring to resident staff are allocated to the institution district.

Live Births

A live birth is defined as the complete expulsion or extraction from its mother of a product of conception, irrespective of the duration of pregnancy, which, after such separation, breathes or shows any other evidence of life such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles, whether or not the umbilical cord has been cut or the placenta is attached.

The New York City Department of Health revised their coding procedure for recording the month prenatal care began (Tables 7, 8, 29) for 1978. As a result, there was a substantial decrease in the number of live births for whom prenatal care was "not stated" and a substantial increase in the number of live births reported with no prenatal care.

"Early prenatal care" (Table 29) is defined as prenatal care during the first trimester of the pregnancy.

The number of out-of-wedlock live births (Table 25) and related data that reflect the marital status of the mother are estimates. New York State Public Health Law prohibits the specific statement on the birth certificate as to whether the child was born in-wedlock or out-of-wedlock.

Prior to 1977 marital status was inferred by examining the statistical information on the certificate of live birth. In 1977 the procedure was modified to also identify out-of-wedlock live births for whom paternity affidavits were filed. These births were previously inferred to have occurred in-wedlock. This modification has resulted in a noticeable increase in the estimated number of out-of-wedlock live births. The background and details of the modified procedure are described in "Quarterly Vital Statistics Review, April-June, 1977".

A premature live birth (Table 29) is defined as a live birth whose weight at birth was under 2501 grams.

Deaths

The cause of death reported in this publication is the underlying cause classified according to the eight revision of the "International Classification of Diseases, Adapted" (ICDA, 8th revision), adopted by New York State in 1969. Historically, several revisions of the ICDA have been used, therefore, it is necessary to employ a "comparability ratio" when comparing cause of death statistics from one revision to another. Comparability ratios have been published by the National Center for Health Statistics and the New York State Department of Health.

Infant and neonatal death statistics published in this report are based on all live births reported during 1978, regardless of birthweight or gestation. No attempt was made to account for the viability of the infant at birth.

Fetal Deaths

A fetal death is defined by New York State Public Health Law to be the death prior to the complete expulsion or extraction from its mother of a product of conception; the death is indicated by the fact that after such separation, the fetus does not breathe or show any other evidence of life such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles.

The fetal death statistics include events occurring within New York City and Upstate New York. Induced terminations of pregnancy are included in the fetal death count unless otherwise indicated.

New York State Public Health Laws require the registration of all fetal deaths regardless of the gestation of the fetus. Unlike birth and death registration, the registration of fetal mortality is not uniform across the United States. In order to provide comparable data, this report presents data for spontaneous fetal deaths of gestation 20 weeks or more. The one notable exception is Table 29 where both total fetal deaths and fetal deaths of gestation 20 weeks or more are reported.

During 1978, the New York City Department of Health employed a new procedure for the reporting of fetal deaths. Separate certificates were used to report spontaneous fetal deaths and induced terminations of pregnancy. A large, unexplained decrease in New York City recorded spontaneous fetal mortality was noted for 1978. The New York City Department of Health has suggested that some of the decline may be due to this reporting change. Efforts are being made to identify any other possible causes for the decline, however, none have been found to date.

Population

Population estimates for July 1, 1976 for New York State counties, cities and villages included in Table 29 were prepared using a component technique in which the natural increase and the estimated net migration between 1975 and 1976 were added to the 1975 base population and then controlled to a provisional State estimate of 18,084,000.

Population estimates for July 1, 1977 for counties, cities and villages were prepared using the same component technique in which the natural increase and the estimated net-migration between 1975 and 1977 were added to the 1975 base population and then controlled to a provisional State estimate of 17,924,000. In making the population estimates for 1976 and 1977, the estimated net-migration was based on the net-migration experience in a given area during the 1973-1975 period.

Population estimates for July 1, 1978 for counties, cities and villages were computed using the same component technique. The natural increase and the estimated net-migration between 1977 and 1978 were added to the 1977 base population. For this set of population estimates, the estimated net-migration was based on the net-migration in a given area during the 1975-1977 period.

In preparing these estimates, institutional population was handled as a special group. The population estimates for the counties and the incorporated cities and villages do not include the inmate population of State and Federal institutions located within their boundaries.

The population estimate for Upstate New York was the sum of population estimates of fifty-seven counties in the State outside New York City and the actual count of the institutional population in these counties in the same year. The New York City population estimates for 1976 and 1977 were obtained as the difference between New York State and Upstate New York population estimates. The population estimate of New York City in 1978 was the sum of population estimates in the five boroughs of the City. The borough population estimates in 1978 were prepared in exactly the same way as the estimates for other counties in the State.

Population estimates for the Health Service Areas (HSA's) and other areas were prepared by adding the rounded population estimates for the respective county and subcounty areas.

Estimates of Population by Age and Sex

The population data by age and sex of July 1, 1978 appearing in Table 1 were estimated in two steps. The estimated number of children under five was developed from birth and death data and corrected for an estimated migration from New York City to Upstate New York. This migration was based on New York State birth and death data and 1970 census data. The population over five was estimated using death data by age and estimated migration data by age based on the censuses of 1960 and 1970. The population in each age group were then uniformly adjusted so that the total of all age groups was consistent with the total July 1, 1978 estimates for New York City and Upstate New York as given in Table 29. The New York State age and sex estimates are the sum of the New York City and Upstate New York estimates.

Maps

This report includes computer generated maps presenting selected vital statistics rates for the counties of New York State. The CMAP program (Scan-Line Choropleth Mapping Program) modified at SUNY Albany was adapted for use on the Department of Health computer by staff of the Office of Biostatistics with assistance from the Office of Electronic Data Processing.

Vital Statistics Rates

The definitions of the rates calculated for this report are given below. In a definition, the numerator reflects the number of vital events counted in a specified period of time, usually a calendar year. The denominator refers to the population count at a specified point in time, usually mid-calendar year. The Figure, Map and/or Table in which the rates appear is given in parentheses.

1. Live Birth Rate: Number of live births, per 1,000 population. (Figure 2; Map 1; Tables 2,29).

2. Fetal Mortality Rate: Spontaneous fetal deaths excluding induced terminations of pregnancy at gestation 20 weeks and over per 1,000 fetal deaths of gestation 20 weeks and over plus live births. A fetal death is defined as death prior to the complete expulsion or extraction from its mother of a product of conception. (Figure 3; Tables 3,29).

3. General Fertility Rate: Number of live births per 1,000 female population between 15 and 44 years of age. (Table 2).

4. Neonatal Mortality Rate: Number of live births dying under 28 days of age per 1,000 live births. (Figure 6; Map 4; Tables 6,29).

5. Infant Mortality Rate: Deaths under one year of age per 1,000 live births. (Figure 5; Map 3; Tables 5,11,29).

6. (Crude) Death Rate: Number of deaths per 1,000 population. (Figure 4; Map 2; Tables 4,11,29).

7. Age-Sex-Specific Death Rate: Number of deaths in a specified age and sex group per 1,000 population in the same age and sex group. Age is decedent's age at last birthday. (Table 11).

8. Cause-Specific Death Rate: Number of deaths from a specified cause or group of causes per 100,000 population. (Tables 12,13,14,29). Exception: The death rate from complications of pregnancy, childbirth and the puerperium is defined as number of deaths from complications of pregnancy, childbirth and the puerperium per 10,000 live births. This death rate is the maternal mortality rate. This cause of death category also includes any maternal death which may have resulted from an induced termination of pregnancy. (Tables 12,13,14).

9. Age-Sex-Adjusted Death Rate (Direct Method): Death rate of a group calculated as a weighted average of the age-sex-specific death rate of the same group. The system of weights is the age-sex-distribution of a population called the Standard Population. In this report the Standard Population is the census count of the New York State population on April 1, 1940. (Figure 4; Table 4).

Small Area Data

In tabulating vital events for cities and villages with 10,000 or more population (Table 29), the problem of small frequencies is incurred. Statistics based on a small number of vital events are subject to a large degree of variability and inferences should be made with care.

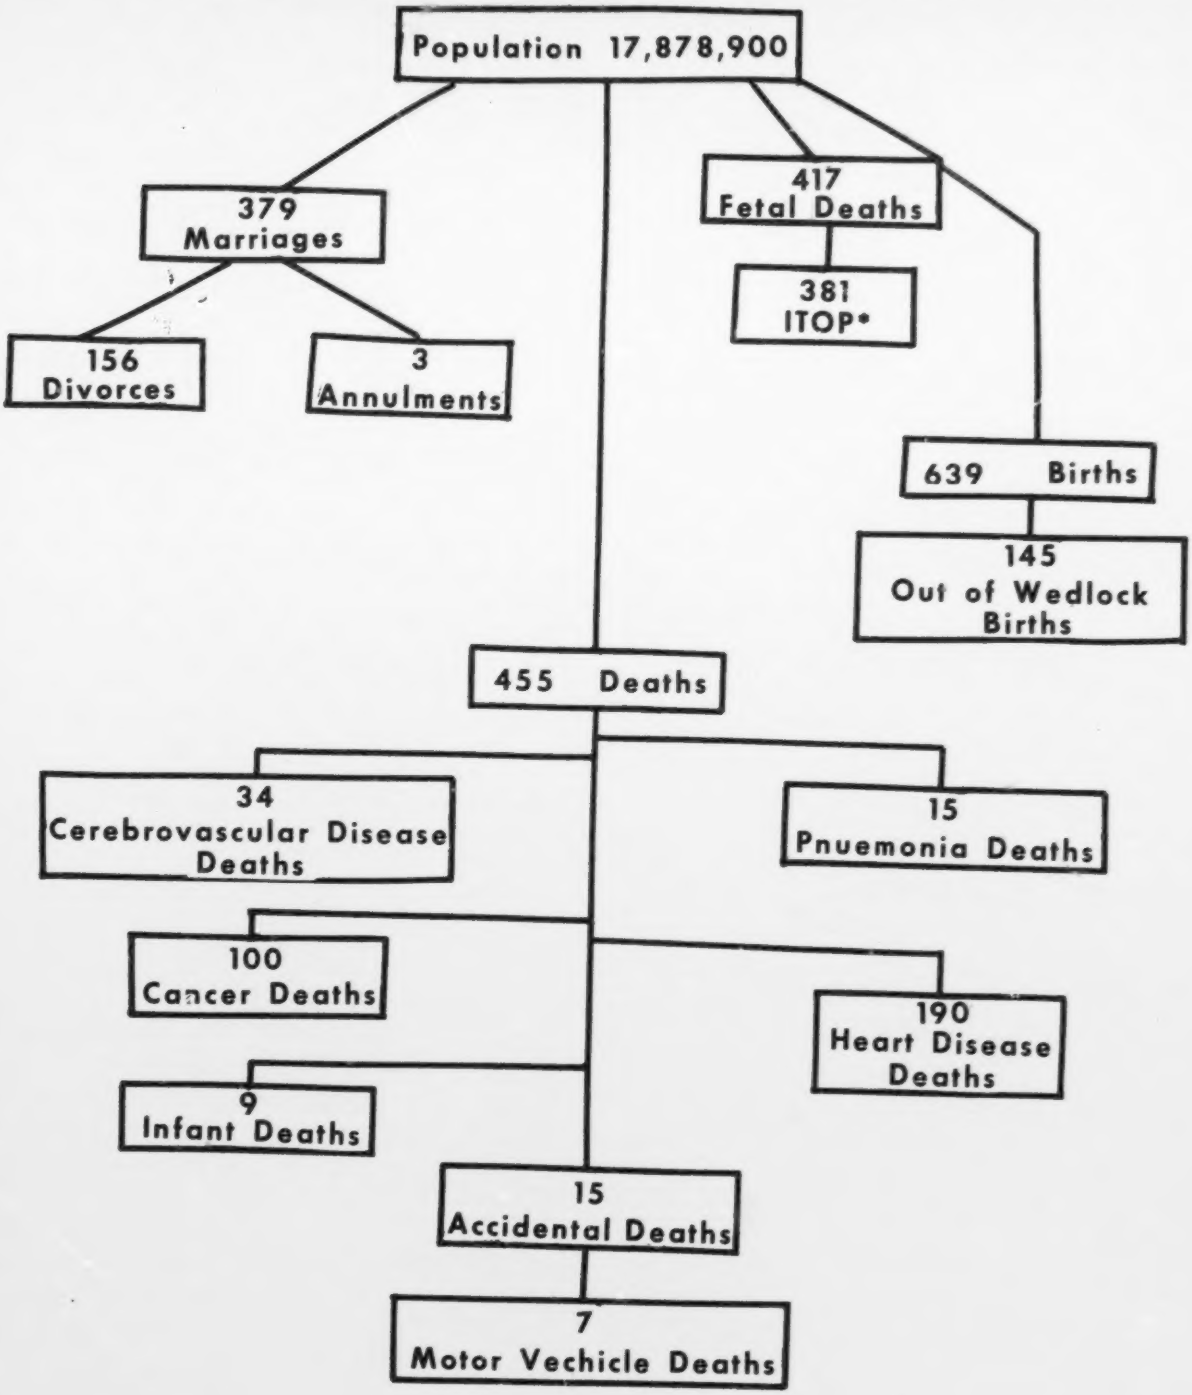
FIGURES, MAPS AND TABLES

The following symbols with their meanings are used in the figures and tables:

Symbol	Meaning
**	Not available/not tabulated
-	Quantity zero

FIGURE 1

EACH DAY DURING 1978, NEW YORK AVERAGED APPROXIMATELY:



Population 17,878,900
379 Marriages
156 Divorces
3 Annulments
417 Fetal Deaths
381 ITOP*
639 Births
145 Out of Wedlock Births
455 Deaths
34 Cerebrovascular Disease Deaths
15 Pnuemonia Deaths
100 Cancer Deaths
190 Heart Disease Deaths
9 Infant Deaths
15 Accidental Deaths
7 Motor Vechicle Deaths

ITOP* denotes induced terminations of pregnancy

TABLE 12. DEATHS AND DEATH RATES FROM SELECTED CAUSES: NEW YORK STATE, 1978

(Numbers after causes of death are category numbers of the Eighth Revision, International Classification of Diseases, First Adopted by New York State for the year 1969.)

Cause of Death	Number	Rate
Tuberculosis (all forms) 010-019	295	1.6
Syphilis and its Sequelae 090-097	10	0.1
Malignant Neoplasms 140-209	36,618	204.8
Buccal Cavity and Pharynx 140-149	837	4.7
Digestive Organs and Peritoneum 150-159	11,105	62.1
Respiratory System 160-163	8,537	47.7
Breast 174	3,713	20.8
Genital Organs 180-187	3,970	22.2
Urinary Organs 188,189	1,685	9.4
Other and Unspecified Sites 170-173,190-199	3,566	19.9
Lymphatic and Hematopoietic Tissues 200-209	3,205	17.9
Diabetes 250	3,219	18.0
Cardiovascular Renal Diseases 390-458,582-584	88,533	495.2
Diseases of the Heart 390-398,402,404,410-429	69,398	388.2
Active Rheumatic Fever 390-392	20	0.1
Chronic Rheumatic Fever 393-398	1,187	6.6
Hypertension with Heart Disease 402,404	687	3.8
Acute Myocardial Infarction 410	27,108	151.6
Other Ischemic Heart Diseases 411-414	37,219	208.2
Other Diseases of the Heart 415-429	3,177	17.8
Hypertension without Mention of Heart Disease 400,401,403	561	3.1
Cerebrovascular Disease 430-438	12,299	68.8
Arteriosclerosis 440	2,073	11.6
Chronic and Unqualified Nephritis and Nephrosis 582-584	683	3.8
Other Diseases of the Circulatory System 441-458	3,519	19.7
Influenza 470-474	159	0.9
Pneumonia 480-486	5,647	31.6
Emphysema 492	1,196	6.7
Peptic Ulcer 531-533	704	3.9
Enteritis and Colitis 535,561-563	436	2.4
Appendicitis 540-543	64	0.4
Hernia and Intestinal Obstruction 550-553,560	462	2.6
Cirrhosis of Liver 571	3,514	19.7
Complications of Pregnancy, Childbirth, and Puerperium 630-678	28	1.2
Congenital Anomalies 740-759	1,002	5.6
Certain Causes of Mortality in Early Infancy 760-769.2,769.4-772,774-778	1,739	9.7
Accidents (Total) 800-949	5,568	31.1
Motor Vehicle 810-823	2,569	14.4
Suicide 950-959	1,641	9.2
Homicide 960-978,990-999	1,816	10.2
All Other Causes	13,532	75.7

See TECHNICAL NOTES for definition of rates.

TABLE 13. DEATHS AND DEATH RATES FROM SELECTED CAUSES: NEW YORK CITY, 1978

(Numbers after causes of death are category numbers of the Eighth Revision, International Classification of Diseases, First Adopted by New York State for the year 1969.)

Cause of Death	Number	Rate
Tuberculosis (all forms) 010-019	187	2.6

FOOTNOTES FOR TABLE 29

1. The term "Upstate" means Rest of State (New York State exclusive of New York City).

2. All vital statistics rates are calculated using residence data. See TECHNICAL NOTES for definition of rates. Table 29 is a summary table of the vital statistics of New York State, 1976-1978. For a complete commentary on the data see, INTRODUCTION, TECHNICAL NOTES, HIGHLIGHTS, and the footnotes to Figures 2-6 and Tables 1-28.

3. A premature birth is defined as a live birth with birthweight under 2501 grams.

4. A birth with early prenatal care is defined as a live birth reporting prenatal care of the mother during the first trimester.

5. Marriage counts by place of occurrence are not available for villages and cities. For 1978 there were 1,881 marriages performed in New York City with licenses issued in Rest of State. The value 1,881 plus the figure for Rest of State (Upstate) given in Table 29 gives the figure for Rest of State which is quoted in Table 27. Monroe County marriage counts are extremely low for 1978 due to the majority of their certificates being received after the marriage files were closed.

6. Dissolutions of marriage by place of occurrence are not available for villages and cities except New York City. The dissolutions of marriage are available by county of occurrence.

7. Percents and rates for all variables presented in the table exclude events in the "not stated" category.

8. The population estimates for the years 1976, 1977 and 1978 for New York State counties and places used in this table are revised estimates prepared by the Demography Unit of the Office of Biostatistics, New York State Health Department and are consistent with the U.S. Bureau of the Census estimates.

VITAL STATISTICS
OF
NEW YORK STATE
1979

New York State Department of Health
David Axelrod, M.D., Commissioner

FOREWORD

This report of the Office of Biostatistics summarizes selected vital and health statistics for the resident population of the State for the year 1979. It presents representative data reflecting the needs and interests of consumers of health information.

These statistics provide a useful, quantitative data base for consumers in the public and private sectors in support of a variety of uses and activities — population dynamics, health economics, planning, program development and evaluation, research, surveillance.

NEW YORK STATE - A CENTURY OF BIRTH, DEATH AND MARRIAGE

Introduction

On May 18, 1880, the New York State Legislature passed the law which established a centralized bureau of Vital Statistics in New York State, and gave it authority to "obtain and preserve...registrations of deaths, births and marriages." Although the laws of 1847 had required counties, cities and towns to collect these data, a lack of uniform standards and the inability of these localities to obtain compliance from undertakers, physicians, midwives and clergymen prevented the collection of complete and accurate information. By 1880 only New York City and 6 of the 24 upstate cities had functioning registration systems. In order to remedy these weaknesses and to insure compliance with this new statute the Vital Statistics Bureau provided all appropriate professional persons under its jurisdiction with uniform documents, procedures and regulations. It even took charge of local registration offices which failed to meet state standards. In order to compel individuals responsible for filing original certificates to comply with the law, state authorities conducted numerous publicity campaigns, sent warning letters to delinquents and fined repeat offenders. By 1915, all the cities, towns and villages in Upstate New York, (New York State exclusive of New York City), were sending timely and substantially complete reports of births, deaths and marriages to state officials in Albany. New York City, alone, continued to maintain its independent registration system.

The first vital statistics reports were mostly narratives which provided graphic descriptions of people, places and illnesses prevalent in the State. About 1890, the reports began to present numerical data which improved in both quality and quantity over the years. An analysis of the figures from these old reports shows the growth of New York State's population and reveals an interesting history of birth, death and marriage in the State.

Population

Since 1880 the population of New York State has grown; increasing from slightly over five million to a peak of about 18.5 million in 1972. The growth which can be attributed to both natural increase and large numbers of immigrants was greatest during the first quarter of the twentieth century. Since 1972 the population of the State has decreased by about 3 percent to slightly under 18 million. Emigration, a depressed birth rate and reduced foreign immigration have contributed to the decline.

Births

For most of the past century birth rates in New York State have followed a cyclical pattern, reflecting the influence of economic and social conditions upon reproduction. From 1908, the first year in which State officials considered the birth registrations complete, to 1918, the end of World War I the crude birth rate[1] was high, that is greater than 22.0 live births per thousand population. In 1914 and 1915 the crude birth rate in New York State peaked at 24.8[2] live births per thousand population. The end of World War I, the influenza epidemic of 1918, the social changes of the "Roaring Twenties" and finally the catastrophic economic conditions of the thirties contributed in turn to a steady marked decline in the birth rate which reached its lowest point, 13.8 live births per thousand population, in 1936, the middle of the Great Depression. From 1933 to 1940 the crude birth rate remained well under 15.0 live births per thousand population. During World War II, 1941-1945 the birth rate began to rise again, this time erratically, and continued climbing after the war until 1957 when it reached a second peak of 22.0 live births per thousand population. The birth rate then leveled off, remaining greater than 20.0 live births per thousand population until 1963. Although the sixties were a time of economic prosperity, social unrest, changes in attitudes toward the family and growing fears of over population gave impetus to another general decline in the birth rate. From 1963 to 1968 the crude birth rate fell from 20.4 to 16.7 live births per thousand population. A slight rise in the rate in 1969 and 1970 appeared to mark the end of this decrease, but with the legalization of abortion in 1970, the birth rate fell again reaching a record low of 13.0 live births per thousand population in 1973, 1975 and 1976. As the decade closed the crude birth rate stabilized at 13.1 live births per thousand population.

In addition to fluctuations in the birth rate, subtle but consistent changes have occurred in the distributions of live births to residents of Upstate New York by maternal age, by birth order (the number of the child in the order of birth) and by mother's marital status.

While females ages 15-44 have always accounted for over 99 percent of the live births, the proportion of live births to women over 29 years of age has decreased in the past 72 years. This reduction has occurred in two stages. The proportion of births to women ages 40 and over has been declining gradually since just after World War I. The decline in the proportion of births to women ages 30 to 39 years has been more rapid appearing chiefly since the legalization of induced abortion in 1970.

The counterbalance to the decrease in births to older women has been the general rise in the proportion of births to women under 30 years of age. The greatest sustained increases have occurred among females ages 10-19 and 25 to 29.

Consistent with this trend has been a reduction in the proportion of births belonging to the higher birth orders. This also was a two phased change. Seventh order births and higher dropped from about 10 percent of the total live births in 1917 to about one percent in the mid to late seventies. The proportion of fourth through sixth order births declined chiefly in the seventies, dropping from an average of 20 percent of the total live births before 1970 to 10 percent in recent years. Concurrent with this change, the percentages of first and second order births have increased while that of third order births has remained fairly constant.

Distributions of live births by the mother's marital status illustrate a change not only in the proportions of out-of-wedlock births but also in society's attitude toward this event. Before 1936 live births in Upstate New York were classified by marital status of the mother. From 1908 to the late twenties about one percent of the live births were called "illegitimate." During the early thirties this figure rose to more than two percent. In 1936 amendments to the Public Health Law prohibited any mention of the mother's marital status on the birth certificates issued in Upstate New York. After an attempt in 1937 to estimate the number of out-of-wedlock births from an absence of information about the father on the birth certificate, the annual reports ceased publishing these data. The estimation procedure resumed in 1970. By that time out-of-wedlock births had increased to well over 10 percent of the total live births and have remained at this level ever since.

Although specific figures on these characteristics are not available for New York City before 1936, distributions of the data obtained since then are similar to those of Upstate New York.

Fetal Deaths, Infant Deaths, Maternal Deaths

Throughout the years, death has unavoidably accompanied the reproductive process in the form of fetal deaths, infant deaths and maternal deaths.

Fetal death (death of the unborn) includes both spontaneous fetal deaths (stillbirths) and induced abortions. In New York State spontaneous fetal deaths to residents accounted for the vast majority of all fetal deaths before the legalization of induced abortion in 1970 and for about 10 percent of the fetal deaths occurring since then. A spontaneous fetal death rate for New York State based on the number of spontaneous fetal deaths with gestations greater than 20 weeks per thousand total births[3] has ranged from 42.7 spontaneous fetal deaths per thousand total births in 1910 to 10.9 spontaneous fetal deaths per thousand total births in 1979. The rate of spontaneous fetal deaths with gestations greater than twenty weeks decreased slowly throughout most of this century. In 1970 the spontaneous fetal death rate still equalled that reported in 1950, about 20 spontaneous fetal deaths per thousand total births. It was not until the legalization of induced abortions that the spontaneous fetal death rate reached the present low level of 10 spontaneous fetal deaths per thousand total births.

In 1967 the Public Health Law was amended to include stillbirths or spontaneous fetal deaths of all gestations. Although vigorous efforts have been made to enforce the new provision, data for spontaneous fetal deaths with gestations less than 20 weeks are incomplete. Many of these early events which occur outside of hospitals are unrecognized and therefore unreported.

In 1970 induced abortion became the prevalent form of fetal death recorded in New York State. Amendments to the Penal Law, which took effect on July first of that year, permitted legal abortions in the State within the first 24 weeks of pregnancy. By the end of 1972 the number of induced abortions performed annually in New York State exceeded a quarter of a million with out-of-state residents accounting for 60 percent of these events. The reason for this phenomenon lay in the fact that between July 1970 and January 1973 New York State was the only state in the Northeastern United States which did not legally limit the reasons for which an abortion might be obtained. When, in January of 1973, the Supreme Court of the United States invalidated all state laws restricting a woman's right to an abortion during the first three months of pregnancy, the number of induced abortions performed in the State decreased by 27 percent and the proportion of these events to out-of-state residents dropped from 61 to 40 percent. Throughout the remainder of the decade the proportions of out-of-state residents terminating their pregnancies in New York State decreased to the present low of 7.0 percent.

Since 1970 the number of induced abortions obtained by New York State residents has increased each year but one, 1975. The ratio of induced abortions to live births has also increased climbing from a low of 354 induced abortions per thousand live births in 1971 to a high of 613 induced abortions per thousand live births in 1979.

Infant deaths, (deaths to children less than one year of age) which have been a scourge to mankind since the beginning of time have decreased dramatically in New York State in this century. In 1904, the first year in which infant deaths were reported separately, the rate was 151 infant deaths per thousand live births. At that time infectious diseases were the principal cause of these deaths. As public sanitation improved and as knowledge concerning the cause, prevention and cure of infectious diseases increased, the infant death rate dropped sharply. By 1921 the infant death rate had fallen to 75 infant deaths per thousand live births; by 1940 it reached 37 infant deaths per thousand live births and continued to decline more gradually until the late seventies when it fell below 14 infant deaths per thousand live births.

The history of maternal deaths, on the other hand, has been different. In New York State before 1915 the maternal death rate averaged 55.5 maternal deaths per ten thousand total births[4]. From that time until the mid thirties the maternal death rate remained essentially unchanged. After a very slight decrease in the late thirties, the maternal death rate began a rapid decline which lasted into the mid fifties. By 1951 the maternal death rate was 5.1 maternal deaths per ten thousand total births, about one eleventh of the rate reported 20 years earlier. It is interesting to note that the factors which so dramatically reduced infant mortality in the early years of this century had little impact upon maternal mortality. It was not until the development and use of sulfa drugs and penicillin that maternal deaths substantially decreased. The decline noted in maternal deaths has continued somewhat less dramatically to the present low of 1.5 maternal deaths per ten thousand total births.

Deaths

In 1890 the Bureau of Vital Statistics reported that the enumeration of deaths for that year in New York State was essentially complete, permitting thereby the calculation of crude death rates.

During the past ninety years, the death rate in the State has gradually but steadily dropped with only temporary increases caused by occasional epidemics of influenza and pneumonia. The highest reported death rate in New York State, 21.4 deaths per thousand population occurred in 1890, the lowest 9.1 in 1979.

The relationship between the death rate and social and economic conditions has not been apparent. Even the war years showed no increases in the death rate because vital statistics records do not include deaths to military personnel outside the boundaries of the United States[5].

The decline in the death rate has not been the only change observed. Shifts in the distribution of deaths by age and by cause have taken place as well.

Throughout the years, the most notable change in the distribution of deaths by age has been a large decline in the percentage of deaths of the young. The earliest and most dramatic decreases have occurred among the very young, children under 5 years of age. In 1900 this group accounted for 33 percent of total deaths. In the 40 years that followed, this figure decreased by 82 percent reaching 6 percent of total deaths in 1940. From 1940 to 1963 the proportions of deaths to the very young stabilized, averaging between 5 and 6 percent a year. Since the mid sixties another decline, of more modest size, has occurred bringing the most recent proportion of deaths to the population under 5 years of age to slightly over 2 percent. The proportions of deaths to individuals ages 5 to 19 years and 20 to 39 years have also decreased but at a much slower rate. Data compiled from 1910 to the late seventies show a decrease from 5½ to one percent of the total deaths for the 5 to 19 year olds and from 16 to 4 percent of the total deaths for those ages 20 to 39 years. In both cases there have been no further reductions in the death rate since 1950.

The proportion of deaths to persons ages 40 to 59 years followed a unique pattern increasing from 20 to 26 percent of the total deaths between 1910 and 1940 and decreasing slowly after that until the late seventies when the proportion reached about 15 percent of the total deaths. As a result of fewer deaths at an early age, persons ages 60 and over have consistently showed increases in the proportion of deaths throughout the years. This proportion ranged from 31 percent in 1910 to 77 percent in 1979.

While complete enumeration of deaths was achieved by 1890, identification of the causes of these deaths was inaccurate and incomplete. Between 1890 and 1910 Vital Statistics summaries reported that over 50 percent of all deaths were in one of the following categories: acute respiratory disease, consumption, diarrhoeal disease, diseases of the central nervous system, unclassified and old age. A subsequent analysis of these early data revealed, for example, that in 1900 tuberculosis was the leading cause of death followed by pneumonia, diarrhea, heart disease and nephritis.

In the early years of the twentieth century cause of death classifications became more exact with the introduction of the International Classification of Diseases. This system established an exclusive category for each diagnostic term of each disease. By 1915 New York State and New York City were classifying deaths according to this system. The first effect of this new procedure was to immediately eliminate "unclassified" as a cause of death and to markedly reduce the number of deaths attributed to senility, old age or ill defined causes. A second result was to provide a basis for comparing the frequencies of various causes of death at different times. It made possible for example, a comparison of cause specific mortality rates occurring in 1979 and 1915, the first year of statewide publication of International Classification of Disease data.

In 1915 heart disease, pneumonia, tuberculosis, nephritis and cerebrovascular disease accounted for 51.6 percent of all deaths with no one cause responsible for more than 14.5 percent of the deaths. A wide variety of pathological conditions, a large proportion of which were infectious, caused the remaining 48 percent of the deaths. In 1979 the situation was different. The five leading causes of death, heart disease, malignant neoplasms, cerebrovascular disease, accident and pneumonia accounted for 78.3 percent of all deaths with heart disease alone causing 42.6 percent of total number of deaths. The remaining 21.7 percent of the deaths were distributed over a wide range of causes with very few deaths from infectious disease.

An analysis of the movement of mortality in New York State reveals four different trends: eradication, reduction, fluctuation and increase. Mortality from cholera, smallpox, diptheria and typhoid has been virtually eradicated. Deaths from tuberculosis, diarrhea, nephritis, measles and other diseases associated with childhood have been substantially reduced. In this category polio holds a unique position because it was not until World War I that it appeared in epidemic form. From World War I until the mid-fifties polio caused numerous deaths the frequency of which declined rapidly with the advent of polio vaccines. Fatalities from cerebrovascular disease, diabetes, pneumonia, influenza, accidents and suicides have varied throughout the years. Even the death rate[6] from the number one killer, heart disease, has begun to decline from the peak of 470.0 deaths per 100,000 population reached in late fifties and early sixties. The only major illness which has shown consistent increases in mortality throughout the past 100 years has been malignant neoplasms which accounted for 66.9 deaths per hundred thousand population in 1900 and 203.6 deaths per hundred thousand population in 1979. However, the rates for both 1978 and 1979 were lower than that reported in 1977, 205.6 deaths per hundred thousand population.

Factors associated with decreases in death are fairly well known: improvements in public sanitation, broad use of immunization, accurate diagnoses of disease, early medical intervention in illnesses, development of improved treatments and especially in the case of infectious disease the use of antibiotics. Two factors are involved in the measured increase of mortality: improved diagnoses, that is assigning diseases to causes previously undetected, and of course increased incidence.

Life Expectancy

The overall decline in mortality in the past 100 years had led to an increase in life expectancy. The life expectancy of males at birth which equalled 45.6 years at the turn of the century rose to 69.9 years by 1978; an increase of 53 percent. The increase in the life expectancy of females at birth was even greater, rising 56 percent from 49.3 years in 1900-1902 to 76.9 years in 1978. In the past 78 years the life expectancy for persons age 65 also increased. For males the increase was modest, a 26 percent gain as life expectancy rose from 11.2 years in 1900-1902 to 14.1 years in 1978. For females the increase in life expectancy was more dramatic, a 51 percent rise from 11.9 years at the turn of the century to 18.0 years in 1978. While life expectancy at birth improved steadily throughout the years, the life expectancy of persons ages 45 and older fluctuated during the first forty years of this century before rising to its present high level. Of the many factors contributing to the increase in life expectancy the reduction in infant mortality has been the most significant.

Marriages

The same law which provided a firm foundation for the registrations of births and deaths in New York State proved quite inadequate in the case of marriages. The law of 1880 required the person solemnizing the marriage to simply file a signed certificate with the local board of health certifying that the ceremony had taken place. Two problems arose from this procedure: an underenumeration of marriages caused by the failure of individuals to file certificates and a large number of marriages of suspicious validity contracted by out of state residents evading restrictive marriage laws in their home states. Therefore in 1907 the

Legislature passed the Marriage License Act which established a procedure for registering marriages that has remained essentially unchanged. Effective January 1, 1908 the city or town clerk was required to issue a license authorizing the performance of a ceremony only after the couple to be married had provided information about previous marriages and divorces and had sworn that no legal impediment to marriage existed. Certification of the ceremony and submission of the signed certificate to the clerk's office by the official solemnizing the event completed the registration process. This piece of legislation so unsettled the populace that there was an unusual surge in marriages in December 1907. In spite of the fuss, state officials reviewing the results of the new procedure were satisfied because the number of suspicious marriages declined and the enumeration appeared substantially complete.

Of all the vital events recorded in New York State marriage is the most sensitive to economic, social legal and demographic conditions. While the financial boom of 1907 gave impetus to a high marriage rate, the Marriage License Law and the financial panic of 1908 coincided with a sharp drop in the number of persons marrying. America's participation in World War I caused broad fluctuations in the frequency of marriage. Marriage rates, which were high during 1917, fell rapidly in 1918, rising sharply again in 1919 and 1920 with the cessation of hostilities. The wide variability in the marriage rates reported between 1930 and 1950 reflected the turbulence of the thirties and forties. The harsh economic realities of the Great Depression lowered the marriage rate for 4 consecutive years 1930-1933. Only with the implementation of the New Deal did economic conditions improve enough to raise the marriage rates in the mid thirties. In the late thirties renewed economic uncertainty and the enactment of laws requiring a premarital blood test for syphilis and a 72 hour waiting period between the issuance of the marriage license and the performance of the ceremony depressed the marriage rates to the record lows observed in 1938 and 1939. Rapid increases in the marriage rates of 1940-1942 appeared with the passage of the Selective Service Training Act in 1940 and America's entrance into World War II in 1941. As the war dragged on the marriage rate declined and remained low for three years, 1943 to 1945. In 1946, the year after Japan's surrender and America's demobilization the marriage rate jumped to a record high of 12.8[8] marriages per thousand population and stayed above 8 marriages per thousand population until after 1953, and the end of the Korean conflict. As social and world conditions settled down in the late fifties and early sixties the marriage rate dropped slowly to an unusually low level, less than 7.5 marriages per thousand population. The dip in the birth rate during the thirties was appearing as a low marriage rate in the fifties. The economic stability of the sixties, the baby boom of the forties and American's slowly increasing involvement in Vietnam contributed to a rising marriage rate in the late sixties and early seventies. However, the peak of this rate, 8.9 marriages per thousand population, fell short of the high rates of former years.

After 1972 the marriage rate steadily declined, a phenomenon which has been associated with the end of the Vietnam conflict, an economic recession and a rejection of traditional attitudes toward marriage by many of the large marriageable population born in the late fifties. The slight rise in marriage rates noted in 1978 and 1979 might presage an end to the great marriage decline of the seventies.

Dissolutions

Before 1968 the New York State Department of Health did not publish data on dissolutions of marriages. Since New York State permitted only annulments or divorces on the grounds of adultery, the dissolution of marriage rate was low; near 0.5 dissolutions per thousand population.

In 1967 an amendment to the Domestic Relations law liberalized the grounds for divorce. During the twelve years in which the new law has been in effect the dissolution of marriage rate in New York State has increased from 0.8 to 3.2[9] dissolutions per thousand population and the divorce rate has risen from 0.6 to 3.2[10] dissolutions per thousand population.

Conclusion

In New York State the vital statistics system has grown from a simple registration of births, deaths and marriages to a complex modern health statistics organization. In 1880 the State Board of Health organized the Bureau of Vital Statistics for the purpose of establishing the basic registration system. In 1901 the bureau became an integral part of the newly formed State Department of Health and consolidated the gains made in early years. Since then the duties of the bureau have so increased in number and complexity that by 1958 the Bureau of Vital Statistics had evolved into the Office of Biostatistics with separate units attending to the various functions.

Today in cooperation with New York City, the Office of Biostatistics not only compiles counts of births, fetal deaths, deaths, marriages and dissolutions of marriage occurring throughout the State, but also stores in a computerized tape system a wide range of the demographic and medical characteristics associated with these vital events. These data serve as the basis for numerous descriptive and analytical studies conducted by department staff and by health professionals throughout the world. In addition to this, the office coordinates the dissemination of health statistics throughout the State.

Whatever the changes in the method, the purpose of vital statistics today remains true to the charge given it in 1880, "the guarding and improvement of the public health, the saving and benefiting of human life."

Joan P. Cooney
Senior Biostatistician

Footnotes

1. Before 1930 birth and death statistics are recorded data. From 1930 to the present data are allocated by place of residence. In an area the size of New York State the differences between resident and recorded data are less than one percent.

2. Based on observed registrations and population estimates available in 1914 and 1915. Other published rates for these are estimates.

3. Live birth plus spontaneous fetal deaths with gestations greater than 20 weeks.

4. Rate per 10,000 live births and spontaneous fetal deaths with gestations greater than 20 weeks. Since 1971 — rate per 10,000 live births.

5. Review of Vital Statistics for year 1942 Vol II p. xxxiv.

6. Number of deaths from specific cause/midyear population x 100,000.

7. Marriage data are recorded.

8. Number marriages per thousand mid-year population.

9. Number dissolutions per thousand mid-year population.

10. Number divorces per thousand mid-year population.

Note on Use of Graphs

Care must be taken in comparing cause specific mortality rates because the various editions of the International Classification of Disease contained different rules for classifying cause of death.

Comparability Ratios make the data between revisions comparable; data from different years within a revision are already comparable. The revisions covered in these graphs are:

Vital Statistics of New York State

INTRODUCTION

This report summarizes selected vital and health statistics for New York State for the calendar year 1979. The information is compiled from the automated vital and health statistics information system of the Office of Biostatistics, New York State Department of Health. The major sources of data are certificates of live birth, death, fetal death, marriage and dissolution of marriage, the federal census and related federal and state information reporting systems. Records of vital events, occurring in 1979, received by the New York State Department of Health after March 31, 1980 are not included in this report. In the case of vital events recorded in New York State the number of records excluded is insignificant. In the case of vital events to New York State residents, recorded outside of New York State, the number of births omitted is negligible while the number of deaths excluded is smaller than one half of one percent of the total resident deaths. Fetal deaths occurring to New York State residents outside of New York State are not reported to the New York State Department of Health.

Vital Statistics in New York State - 1979 - is the one hundredth annual summary of vital events in the state. This report prepared by the Office of Biostatistics is only one of several reports originating in this Office. Other available publications are:

> The Vital Statistics Review - a quarterly report of selected preliminary vital and health statistics plus special articles relating to vital events in New York State.
>
> Selected Health Statistics for Hospitals New York State Exclusive of New York City - an annual summary of the characteristics of live births, fetal deaths and neonatal deaths occurring in hospitals in Upstate New York.
>
> Induced Abortions Recorded in New York State - an annual analysis of selected characteristics of induced abortions performed in New York State along with a five year summary.

A list of titles and authors of the special articles that have appeared in these periodicals may be found at the end of this report.

Single copies of these publications are available without charge as long as supplies last. Inquiries should be addressed to the Office of Biostatistics, New York State Department of Health.

HIGHLIGHTS

Population

New York State's estimated population for July 1, 1979 equalled 17,939,800. In spite of a 0.3 percent increase over the 1978 estimate, the 1979 figure remained 2 percent smaller than the population reported in 1970. Both New York City and Upstate New York (New York State exclusive of New York City) showed small increases, resulting in July first estimates of 7,234,300 for New York City and 10,705,500 for Upstate. A natural increase of 71,901 persons reduced by a loss of 11,001 individuals through migration produced the current estimate.

In New York State in 1979 the population sex ratio remained unchanged at 111 females for every 100 males. The age distribution in the State also remained relatively stable. About 48 percent of New York State's residents were 30 years of age or younger; 30 percent were less than 20 years old and 12 percent were 65 years of age or older. Women ages 15-44, the child bearing years, comprised 23.6 percent of the total population.

Live Births

In 1979 there were 234,867 resident live births in New York State; 101,591 in New York City and 133,276 in Upstate New York (New York State exclusive of New York City). This statewide total was 0.6 percent greater than that reported in 1978. The small increase was the result of combining the number of resident live births in Upstate New York, which increased 2 percent over the 1978 level with the number of resident live births in New York City which decreased one percent in the same period.

New York State's crude birth rate in 1979 equalled that reported in 1978, 13.1 live births per thousand population. The increase which had been observed in the number of live births in the State in 1979 was matched by an increase in the 1979 estimated population resulting thereby in an unchanged birth rate. The 1979 birth rate has continued the trend of low birth rates observed in this State since 1973. The only exception was 1977 when the rate rose to 13.4 live births per thousand population.

The National Center for Health Statistics reported a provisional U.S. birth rate for 1979 of 15.8 live births per thousand population. This figure, which was 3 percent larger than the 1978 U.S. rate, exceeded the 1979 New York State rate by 20.6 percent.

In 1979 New York State's general fertility rate dropped about 1 percent to 55.5 live births per thousand females ages 15-44, the lowest rate noted since 1939 when the fertility rate fell to 54.7 live births per thousand females ages 15-44. The 1979 fertility rate was also 33 percent smaller than the rate observed in 1970.

In 1979 New York City reported a 2.8 percent decrease in its general fertility rate, while Upstate showed an increase of less than 0.5 percent. In 1979 the U.S. provisional fertility rate of 68.0 live births per thousand females ages 15-44 exceeded New York State's 1979 general fertility rate by 22.5 percent. Unlike the New York State rate, the national fertility rate increased in the last year.

Teenage fertility in New York State fell to 18.5 live births per thousand females ages 10-19. This figure was 1.6 percent smaller than the 1978 level and 26.3 percent smaller than the 1970 rate.

An analysis of the distributions of 1979 resident live births by color, sex, maternal age, marital status of mother, birthorder, birthweight and prenatal care revealed no major changes in birth characteristics.

The color distribution of resident live births in New York State in 1979 showed 179,200 white live births and 54,807 nonwhite live births. Both white and nonwhite resident live births increased in 1979, the former by 0.6 percent, the latter by 2.5 percent. A 2 percent decrease in the number of white live births to New York City residents reduced the impact of the increase noted in the white live births to Upstate residents. Increases in the number of nonwhite live births in both New York City and Upstate New York contributed to the statewide gain for nonwhites in 1979. Although the number of live births increased for both color groups, the ratio of white to nonwhite live births remained essentially unchanged at 3.3 to 1.

The ratio of male births to female births in New York State in 1979, 1,054 male births to every thousand female births, equalled that reported in 1978. Between 1978 and 1979 the sex ratio increased for white live births rising from 1,058 to 1,061 male births per 1,000 female births and decreased for nonwhite live births dropping from 1,040 to 1,031 male births per thousand female births.

Live births by mother's age showed that 28,103 or 12.0 percent of live births were to teenage mothers, 146,569 or 62.4 percent to women ages 20-29 years, 57,935 or 24.7 percent to those 30-39 years and less than one percent or 2,243 to women 40 years and older. The increase in the number of live births noted in 1979 resulted chiefly from an increase in live births to mothers ages 30-39 years. Live births to mothers ages 40 years and older dropped slightly continuing the trend observed throughout the seventies. All maternal cohorts less than 30 years of age registered a decline in 1979. The largest decrease occurred among mothers ages 10-19 years. The number of live births to teenagers, 28,103, showed a 2.8 percent decline from the 1978 level and a 31.2 percent decrease from 1970. The proportion of mothers who were teenagers, 12.0 percent, fell 3.2 percent from 1978 and 12.4 percent from 1973 the year in which the percentage of teenage mothers peaked. An analysis of maternal age patterns by race revealed that the number of white live births decreased among mothers less than 30 years of age, while nonwhite live births declined only among mothers ages 10-19 years and 40 years and older. Although the number of live births to both white and nonwhite teenagers declined in 1979, the proportion of nonwhite live births to teenagers remained at the level reported in 1978 almost 40 percent. This was substantially larger than the percentage of nonwhite live births found in the total population, 23 percent.

The median age of New York State residents giving birth in 1979 was 26.3 years, a slight increase over the 26.2 years reported in 1978 and a 4.4 percent increase in the median age noted in 1970. Throughout the seventies the maternal median age increased slowly but steadily. The median age of both white and nonwhite mothers rose in 1979 to 26.6 and 25.0 years respectively.

Since 1936, Public Health Law has prohibited any mention of the mother's marital status on the birth certificate. However an analytic procedure described in the

Technical Notes permits inferences to be made concerning the number of out of wedlock live births. In 1979 the number of out of wedlock resident live births in New York State numbered 53,748 which was 1.6 percent larger than the number reported in 1978. The proportion of these births rose 0.9 percent to 22.9 percent of all resident live births. Out of wedlock births varied by race and age of mother. About 13.8 percent of the 1979 white live births occurred out of wedlock, while 52.5 percent of the nonwhite live births were out of wedlock. The distribution of out of wedlock live births by maternal age showed that females ages 10-19 had the largest proportion of out of wedlock births, 63.3 percent, while females ages 30-34 years had the smallest, 10.9 percent. In general the percentages of out of wedlock births among all age cohorts varied less than one percent in the last 2 years.

About 74.3 percent or 174,521 of the 1979 New York State resident live births were first or second order births, 15.1 percent or 35,433 third order births, 9.5 percent or 22,396 birth orders 4 through 6 and 1.1 percent or 2,501 birth orders 7 or more. Small increases were noted both in the numbers and the proportions of first and second order births. In general all birth orders continued the trend prevalent throughout the seventies, that is increases in lower and decreases in higher birth orders. The distribution of live births by birth order for whites and nonwhites revealed that the percentage of second order live births for whites exceeded that for nonwhites and the percentage of live births in orders 4 through 6 for nonwhites was greater than that for whites. In all other birth orders the proportions were similar for the two groups.

About 7.7 percent or 18,075 of the 1979 New York State resident live births weighed less than 2,501 grams at birth, a fact which classified them as "premature" or "low birthweight" babies. This proportion, an important indicator of fetal growth and health, has remained essentially unchanged for the past two years. The proportion of infants with low birthweights is known to vary with race and maternal age. In 1979 the proportion of nonwhite live births that were premature was almost twice that found among whites. Within each color group the percentage of premature infants has varied only slightly over the years. For nonwhites, the proportion of premature infants dropped 0.8 percent to 12.2 percent of the total nonwhite live births; for whites this proportion remained unchanged at 6.3 percent. When low birthweight and maternal age were examined, the highest proportions of low birthweight infants were found among mothers less than 20 and greater than 40 years of age. The lowest proportion of low birthweight infants occurred among women ages 25-34 years. A comparison of data for 1978 and 1979 revealed increases of more than 5 percent in the proportions of low birthweight infants to mothers 35-39 and 10-14 years of age and decreases in this figure among women ages 20-24.

In New York State in 1979, 228,224 or 97 percent of the total live births reported data identifying the first month of prenatal care. Of these, 152,114 or 64.8 percent began prenatal care during the first trimester while 8,389 or 3.6 percent received no prenatal care at all. The 1979 figures showed improvement over the 1978 level of prenatal care with both the number and proportion of live births with care in the first trimester increasing by about 3 percent and the number and proportion in all other categories decreasing 5 percent. As with many of the other characteristics of live births, prenatal care varied with race and maternal age. In 1979 about 72.1

percent of white live births received prenatal care in the first trimester as compared to 41.2 percent of nonwhite births. Only 2.1 percent of white births had no prenatal care in contrast to 8.2 percent of the nonwhites. For both whites and nonwhites however, 1979 data moved in the direction of earlier prenatal care. The distribution of prenatal care by maternal age revealed that the largest proportions of those with the least prenatal care were mothers less than 20 years and greater than 40 years of age. Those with most prenatal care were women ages 25-34 years. It is interesting to note that the distributions of prenatal care by mothers age and prematurity by mothers age were very similar.

In New York State in 1979 most characteristics of total live births showed a change of less than one percent. The only exception to this was a 1.6 percent increase in the total number of out of wedlock live births. The variations which occurred to specific age or color groups either were very small or counterbalanced one another, producing the small variations noted in statewide values.

Fetal Mortality

In New York State in 1979 resident spontaneous fetal deaths which accounted for less than 9 percent of the total resident fetal deaths increased 6.2 percent to a total of 13,873 and the spontaneous fetal death rate rose 5.3 percent to 55.7 spontaneous fetal deaths per thousand total births. Decomposition of these statewide figures into New York City and Upstate New York components revealed a substantial difference between the two areas. In New York City there was an 11.3 percent decrease in the number of resident spontaneous fetal deaths which, taken with a decrease in the number of live births, produced no change in the spontaneous fetal death rate. In Upstate New York, an 11.3 percent increase in the number of resident spontaneous fetal deaths in combination with a 2 percent increase in the number of live births increased the spontaneous fetal death rate 8.8 percent to 60.3 spontaneous fetal deaths per thousand total births.

An examination of 1978 and 1979 data suggests that the increase in spontaneous fetal mortality may be the result of improved reporting of this event. The underreporting of spontaneous fetal death, particularly among early gestations, is generally accepted. While there was an increase in the number of late spontaneous fetal deaths (20 weeks or more gestation) the bulk of the increase occurred in early spontaneous fetal deaths. This, together with the fact that the increase occurred across all maternal age cohorts and was widely distributed across the State makes the improved reporting hypothesis plausible. More effective delivery of health services, reaching a broader population base would also contribute to improved vital statistics reporting. The early attainment of prenatal care is but one indication of this.

In order to provide data comparable to that from other states an analysis of spontaneous fetal deaths with gestations 20 weeks or more revealed increases in both the number and the rate of these events. In 1979 the number of resident spontaneous fetal deaths of 20 weeks or more gestation in the State rose to 2,596, an increase of 7.5 percent over the 1978 level while the rate increased 6.8 percent to 10.9 spontaneous fetal deaths of 20 weeks or more gestation per thousand live births and spontaneous fetal deaths of 20 weeks or more gestation. The increases in these spontaneous fetal deaths occurred in New York City and in Upstate New York both of which reported increased numbers of pregnancies to nonwhites who traditionally have higher spontaneous fetal death rates than whites.

Induced abortions, both recorded and resident, also showed statewide increases in 1979. Although the number of induced abortions which occurred in New York State rose 0.7 percent to 154,805, this recorded total remained much smaller than those reported in 1971 and 1972. The small increase in the number of recorded induced abortions resulted from a 3.4 percent rise in induced abortions to New York State residents and a 25.1 percent decline in the number of abortions to out of state residents. Between 1978 and 1979 the proportion of induced abortions to out of state residents recorded in New York State fell from 9.5 percent to 7.0 percent. The 3.4 percent gain noted in the induced abortions to New York State residents (143,909) resulted from increases in the number of resident induced abortions both in New York City (93,569) and Upstate New York (50,340). In each of these areas increases in induced abortions occurred among women less than 35 years of age. Induced abortions to women ages 35 years and over decreased slightly.

The ratio of induced abortions to live births in New York State in 1979 was 613 induced abortions for every thousand live births, up from the 596 induced abortions per thousand live births reported in 1978. Women ages less than 20 and greater than 40 years continued to experience more induced abortions than live births.

The publication entitled "Induced Abortions Recorded in New York State - 1979" will present a more detailed analysis of the characteristics of these events.

Mortality

Resident deaths in New York State decreased 1.9 percent in 1979 to 162,966. The 91,187 resident deaths in Upstate New York represented a 2.3 percent decrease while the 71,779 resident deaths in New York City equalled a 1.5 percent decline. The crude death rates for New York State, Upstate New York and New York City all decreased in 1979. The statewide crude death rate dropped 2.2 percent to 9.1 deaths per thousand population; the Upstate rate fell 2.3 percent to 8.5 deaths per thousand population while New York City's rate decreased 1.5 percent to 9.9 deaths per thousand population. In each of these areas the 1979 crude death rate was the lowest reported since 1890, the first year of complete death registration in the State. The National Center for Health Statistics reported a provisional U.S. crude death rate for 1979 of 8.7 deaths per thousand population which was 1.1 percent lower than the 1978 U.S. provisional rate and 4.4 percent lower than the 1979 New York State rate. The age-sex adjusted death rate for New York State was 6.2 deaths per thousand population and like the crude rate, reached a record low value.

In 1979 the crude death rate for males decreased 3 percent to 10.0 male deaths per thousand male population while the female death rate fell 2.4 percent to 8.2 female deaths per thousand female population. For all age cohorts, male death rates exceeded those for females. In 1979 death rates increased among males ages 15-44 years, remained constant for ages 1-14 years and declined for males ages 45 years and over. For females the death rates declined for age cohorts 25-34 years and 45 years and older. Death rates in all other age cohorts remained constant.

Although total deaths have declined in New York State, deaths to nonwhites have not. In 1979 there were 19,274 deaths to nonwhite residents reported in the state. This was a 1.1 percent increase and brought the proportion of nonwhite deaths to 11.8 percent of all resident deaths.

The cause of death classifications for 1979 New York State resident deaths were based on the newly adopted Ninth revision of the International Classification of Diseases. In this revision there have been major reclassifications of a number of causes of death resulting in substantial differences in the enumeration of deaths from these causes. In order to analyze mortality trends between the Eighth and Ninth Revisions, it is necessary to apply comparability ratios to data coded by Eighth Revision criteria. All comparisons made in this analysis were based on data adjusted using U.S. comparability ratios published by the National Center for Health Statistics. Since these ratios are not specific to New York State, these comparisons should be interpreted somewhat cautiously.

In 1979 the five leading causes of death in New York State were diseases of the heart, malignant neoplasms, cerebrovascular disease, accidents and pneumonia. The only change from 1978 has been the rise of accidents from fifth to fourth place and the drop of pneumonia from fourth to fifth. In 1979 the five leading causes of death accounted for 78.3 percent of all deaths.

Deaths from diseases of the heart accounted for 42.6 percent of all resident deaths in 1979 and numbered 69,462. Although the number of these deaths increased slightly over the 1978 level, the death rate, 387.2 heart disease deaths per hundred thousand population, decreased, continuing the downward trend observed during the seventies. The major components of diseases of the heart remained: myocardial infarction at a rate of 151.8 myocardial infarction deaths per hundred thousand population and ischemic heart disease with a rate of 178.0 ischemic heart disease deaths per hundred thousand population. In 1979 the death rate due to heart disease for males, 416.6 male deaths per hundred thousand male population, remained greater than that for females. However, during this time the death rate among males from this cause decreased, while the female death rate from heart disease rose to 360.7 female deaths per hundred thousand female population.

About 22 percent of the 1979 resident deaths were caused by malignant neoplasms. The number of these deaths declined in 1979 by 0.3 percent to 36,256. The death rate due to malignant neoplasms fell to 203.6 deaths per hundred thousand population. This was the second consecutive year in which the death rate from malignant neoplasms decreased. This trend appears to have reversed, at least temporarily, the trend followed since the early years of the twentieth century. The distribution of fatal malignant neoplasms by site showed about 31 percent in the digestive system, 23 percent in the respiratory system, 15 percent in the genito-urinary system and 10 percent in the breast. As with diseases of the heart, the death rate for males from malignant neoplasms exceeded that for females. For malignant neoplasms however, the rates for both males and females declined from the level of the previous year, one percent and 0.4 percent respectively. The relatively small decrease for women resulted chiefly from the fact that decreases in deaths from malignant neoplasms of the digestive system, genito-urinary system and breast were offset by an increase in deaths from malignant neoplasms of the respiratory system. The female death rate from malignant neoplasms of the respiratory system increased by nearly 70 percent during the seventies.

Cerebrovascular disease, the third leading cause of death, caused about 7 percent of the total resident deaths. In 1979 deaths from cerebrovascular disease decreased 5.2 percent to 11,569. The death rate for this cause also decreased, dropping to 65.0 cerebrovascular deaths per hundred thousand population. This continued a decline observed throughout the seventies. As in the past more women then men died from cerebrovascular disease with more than 85 percent of all persons dying from this cause over the age of 60 years.

Accidents, which were responsible for 3.4 percent of all resident deaths, decreased 3.9 percent to 5,350. The death rate from accidents decreased during the year to 29.8 accidental deaths per hundred thousand population. Motor vehicle accidents accounted for about 48 percent of all accidental deaths, while accidents in the home were responsible for 23 percent of these events. More men than women died from accidents. For men these deaths were distributed fairly uniformly across all ages; for women more than 50 percent of these deaths occurred at age 60 years and older.

In 1979, both the number and the rate of deaths from pneumonia dropped, making it the fifth leading cause of death. The 4,658 pneumonia deaths produced a rate of 26.0 pneumonia deaths per 100,000 population, the lowest reported in the seventies. Although pneumonia mortality has in general declined since the turn of the century, occassional increases have occurred, especially when influenza has reached epidemic proportions. Since 1979 was a year of few influenza deaths, the pneumonia death rate declined. In 1979 almost equal numbers of men and women died from pneumonia with about 85 percent of these deaths occurring to persons 60 years of age and older. Several other causes are listed on Table 12 which showed decreased numbers including diabetes, arteriosclerosis and emphysema. Suicides remained about the same, while acute polomyelitis, cirrhosis of the liver and homicide increased. Changes in the Ninth revision has produced major discontinuities in the mortality trends of nephritis, nephrosis, enteritis and colitis.

While the above described causes of death for the population as a whole, the causes of death among nonwhites differed from those for whites. Homicide and cirrhosis of the liver replaced accidents and pneumonia as fourth and fifth in the five leading causes of death among nonwhites.

Infant mortality in New York State in 1979 decreased 2.2 percent to 3,177 deaths, producing a record low infant mortality rate of 13.5 infant deaths per 1,000 live births. In both Upstate New York and New York City both the numbers of infant deaths and the infant mortality rates declined to new lows. In Upstate New York there were 1,586 infant deaths, a rate of 11.9 infant deaths per thousand live births. In New York City the 1,591 infant deaths yielded a rate of 15.7 infant deaths per thousand births. The National Center for Health Statistics reported a provisional infant mortality rate for 1979 of 13.0 infant deaths per thousand live births. This rate which was 4.4 percent lower than the 1978 U.S. provisional rate was also 3.7 percent lower than the 1979 New York State rate. About 71 percent or 2,266 of all infant deaths were younger than 28 days; 1,270 or 40 percent of infant deaths occurred within 24 hours after birth. An analysis of infant deaths by race showed 1,037 infant deaths to nonwhites which resulted in a nonwhite infant mortality rate of 18.9

infant deaths per thousand live births. Although this rate was higher than that for whites it was a 10 percent decrease from the 1978 level. Leading causes of infant deaths for both whites and nonwhites in 1979 were congenital anomalies, short gestation - low birthweight, and respiratory distress syndrome. These causes accounted for 1,485 or 47 percent of all infant deaths. The cause of death described in the Ninth Revision as "short gestation - low birthweight" was comparable to the Eighth Revision code labeled "immaturity unqualified". "Respiratory distress syndrome" listed in the Ninth Revision has no similar code in the Eighth Revision.

Marriages

In 1979 the number of marriages performed in New York State increased 4.7 percent to 144,088. Upstate New York accounted for 82,062 of these events, an increase of 1.7 percent and New York City for 62,026, a 7.3 percent increase. In all areas the crude marriage rate increased, rising to 8.0 marriages per thousand population for the entire state, to 7.7 marriages per thousand population for Upstate New York and to 8.6 marriages per thousand population for New York City. This has been the second consecutive statewide increase in the marriage rate, reversing the decline noted from 1972-1977. The U.S. provisional marriage rate for 1979 of 10.5 marriages per thousand population was 3 percent larger than the provisional rate for 1978 and 31 percent greater than the New York State rate. While the New York State marriage rat rose in 1978 and 1979, the U.S. rate has been increasing since 1976.

In addition to increased numbers of marriages an increase in the median age of those marrying has been noted. In 1979 the median age for brides rose to 23.7 years in comparison to the 22.3 years in 1978. For grooms the median age has risen from 24.5 to 25.9 years during the same period. These increases continued the trend noted since the early seventies.

Dissolutions of Marriage

In 1979 dissolutions of marriage in New York State (divorces, annulments, others[1]) numbered 64,420, 10.9 percent larger than the total number of dissolutions of marriage reported in 1978. The crude rate based on this 1979 total figure, 3.6 dissolutions of marriage per thousand population was 12.5 percent larger than the 1978 rate. In New York City and in Upstate New York both the number and the rate of dissolutions of marriage increased with the gain in Upstate New York exceeding that noted in New York City. In spite of the substantial rise observed in the New York State dissolution of marriage rate, it was 32 percent smaller than the 1979 U.S. provisional divorce rate of 5.3 divorces per thousand population reported by the National Center for Health Statistics. The U.S. divorce rate[2] also showed an increase over the previous year.

Of the 64,420 dissolutions of marriage, 63,300 or 98 percent were divorces. The median duration of all marriages terminated in the state in 1979 was 8.4 years up from the 7.3 years reported in 1978.

[1] Dissolution according to Article 12 of the Domestic Relations Law.
[2] U.S. divorce rate includes annulments.

TECHNICAL NOTES

Registration

New York State is divided into two Registration Areas, New York City and Upstate New York (New York State exclusive of New York City). New York City is comprised of the five counties of Bronx, Kings (Brooklyn), Queens, New York (Manhattan) and Richmond; the remaining 57 counties comprise Upstate New York. It is possible to publish summary vital statistics for total New York State through a cooperative exchange of data between the two Registration Areas. The Office of Biostatistics of the New York State Department of Health processes data from live birth, death and fetal death certificates recorded in Upstate New York and through a cooperative arrangement tabulates data on live births, deaths and fetal deaths recorded in New York City and on live births and deaths recorded out of State but in the United States or Canada.

Residence

Unless otherwise specified in the titles of the tables, the vital statistics presented in this report are based on the vital records of events to New York State residents occurring in the United States and Canada. The events are allocated to the place of usual residence as reported on the certificates with the following exception. Vital events occurring to inmates of state and federal institutions are allocated to their residence at the time of admission. Vital events occurring to resident staff are allocated to the institution district.

Live Births

A live birth is defined as the complete expulsion or extraction from its mother of a product of conception, irrespective of the duration of pregnancy, which, after such separation, breathes or shows any other evidence of life such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles, whether or not the umbilical cord has been cut or the placenta is attached.

"Early prenatal care" (Table 29) is defined as prenatal care during the first trimester of the pregnancy.

The number of out-of-wedlock live births (Table 25) and related data that reflect the marital status of the mother are estimates. New York State Public Health Law prohibits the specific statement on the birth certificate as to whether the child was born in-wedlock or out-of-wedlock.

Prior to 1977 marital status was inferred by examining the statistical information on the certificate of live birth. In 1977 the procedure was modified to also identify out-of-wedlock live births for whom paternity affidavits were filed. These births were previously inferred to have occurred in-wedlock. This modification has resulted in a noticeable increase in the estimated number of out-of-wedlock live births. The background and details of the modified procedure are described in "Quarterly Vital Statistics Review, April-June, 1977."

A premature live birth (Table 29) is defined as a live birth whose weight at birth was under 2501 grams.

Deaths

The cause of death reported in this publication is the underlying cause classified according to the Ninth revision of the "International Classification of Diseases" (ICD, 9th revision), adopted by New York State in 1979. Historically, several revisions of the ICDA have been used, therefore, it is necessary to employ a "comparability ratio" when comparing cause of death statistics from one revision to another. Comparability ratios have been published by the National Center for Health Statistics.

Infant and neonatal death statistics published in this report are based on all live births reported during 1979, regardless of birthweight or gestation. No attempt was made to account for the viability of the infant at birth.

Fetal Deaths

A fetal death is defined by New York State Public Health Law to be the death prior to the complete expulsion or extraction from its mother of a product of conception; the death is indicated by the fact that after such separation, the fetus does not breathe or show any other evidence of life such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles.

The fetal death statistics include events occurring within New York City and Upstate New York. Induced abortions are included in the fetal death count unless otherwise indicated.

New York State Public Health Laws require the registration of all fetal deaths regardless of the gestation of the fetus. Unlike birth and death registration, the registration of fetal mortality is not uniform across the United States. In order to provide comparable data, this report presents data for spontaneous fetal deaths of gestation 20 weeks or more. The one notable exception is Table 29 where both total fetal deaths and fetal deaths of gestation 20 weeks or more are reported.

Population

Population estimates for July 1, 1977 for New York State counties, cities and villages included in Table 29 were prepared using a component technique in which the natural increase and the estimated net migration between 1975 and 1977 were added to the 1975 base population and then controlled to a provisional State estimate of 17,924,000. For this set of population estimates, the estimated net-migration was based on the net-migration experience in a given area during the 1973-1975 period.

Population estimates for July 1, 1978 for counties, cities and villages were prepared using the same component technique in which the natural increase and the estimated net-migration between 1977 and 1978 were added to the 1977 base population. In making the population estimates for 1977 and 1978, the estimated net-migration was based on net-migration experience in a given area during the 1975-1977 period.

Population estimates for July 1, 1979 counties, cities and villages were computed using the same component technique. The natural increase and the estimated net-migration between 1977 and 1979 were added to the 1977 base population.

In preparing these estimates, the institutional population was handled as a special group. The population estimates for the counties and the incorporated cities and villages do not include the inmate population of State and Federal institutions located within their boundaries. New York City and its constituent boroughs (counties) estimates are exceptions and they do include institutional population.

The population estimate for Upstate New York was the sum of fifty-seven counties in the State outside New York City and the actual count of the institutional population in these counties in the same year. The New York City population estimate for 1977 was obtained as the difference between New York State and Upstate New York population estimates. The population estimates for New York City for the years 1978 and 1979 were obtained by adding the population estimates in the five boroughs of the city. The borough population estimates in 1978 were prepared in exactly the same way as the estimates for other counties in the State. The borough population estimates in 1979 were again computed using the same component method but it was assumed that the 1977-1979 net-migration for each borough was only half as large as the 1975-1977 for the same borough.

Population estimates for the Health Service Areas (HSA's) and other areas were prepared by adding the rounded population estimates for the respective county and subcounty areas.

Estimates of Population by Age and Sex

The population data by age and sex of July 1, 1979 appearing in Table 1 were estimated in two steps. The estimated number of children under five was developed from birth and death data and corrected for an estimated migration from New York City to Upstate New York. This migration was based on New York State birth and death data and the corrected 1970 census data. The population over five was estimated using death data by age and estimated migration data by age based on the censuses of 1960 and 1970. The population in each age group were then uniformally adjusted so that the total of all age groups was consistent with the total July 1, 1979 estimates for New York City and Upstate New York as given in Table 29. The New York State age and sex estimates are the sum of the New York City and Upstate New York estimates.

Maps

This report includes computer generated maps presenting selected vital statistics rates for the counties of New York State. The CMAP program (Scan-Line Choropleth Mapping Program) modified at SUNY Albany was adapted for use on the Department of Health computer by staff of the Office of Biostatistics with assistance from the Office of Electronic Data Processing.

Vital Statistics Rates

The definitions of the rates calculated for this report are given below. In a definition, the numerator reflects the number of vital events counted in a specified period of time, usually a calendar year. The denominator refers to the population count at a specified point in time, usually mid-calendar year. The Figure, Map and/or Table in which the rates appear is given in parentheses.

1. Live Birth Rate: Number of live births, per 1,000 population. (Figure 2; Map 1; Tables 2,29,31,32,33).

2. Spontaneous Fetal Mortality Rate: Spontaneous fetal deaths with gestation 20 weeks and over excluding induced abortions per 1,000 spontaneous fetal deaths of gestation 20 weeks and over plus live births. A fetal death is defined as death prior to the complete expulsion or extraction from its mother of a product of conception. (Figure 3; Tables 3,29,31,32,33).

3. General Fertility Rate: Number of live births per 1,000 female population between 15 and 44 years of age. (Table 2).

4. Neonatal Mortality Rate: Number of live births dying under 28 days of age per 1,000 live births. (Figure 6; Map 4; Tables 6,29,31,32,33).

5. Infant Mortality Rate: Deaths under one year of age per 1,000 live births. (Figure 5; Map 3; Tables 5,11,29,31,32,33).

6. (Crude) Death Rate: Number of deaths per 1,000 population. (Figure 4; Map 2; Tables 4,11,29,31,32,33).

7. Age-Sex-Specific Death Rate: Number of deaths in a specified age and sex group per 1,000 population in the same age and sex group. Age is decedent's age at last birthday. (Table 11).

8. Cause-Specific Death Rate: Number of deaths from a specified cause or group of causes per 100,000 population. (Tables 12,13,14,29,34,35,36). Exception: The death rate from complications of pregnancy, childbirth and the puerperium is defined as number of deaths from complications of pregnancy, childbirth and the puerperium per 10,000 live births. This death rate is the maternal mortality rate. This cause of death category also includes any maternal death which may have resulted from an induced abortion. (Tables 12,13,14).

9. Age-Sex-Adjusted Death Rate (Direct Method): Death rate of a group calculated as a weighted average of the age-sex-specific death rate of the same group. The system of weights is the age-sex-distribution of a population called the Standard Population. In this report the Standard Population is the census count of the New York State population on April 1, 1940. (Figure 4; Table 4).

Small Area Data

In tabulating vital events for cities and villages with 10,000 or more population (Table 29), the problem of small frequencies is incurred. Statistics based on a small number of vital events are subject to a large degree of variability and inferences should be made with care.

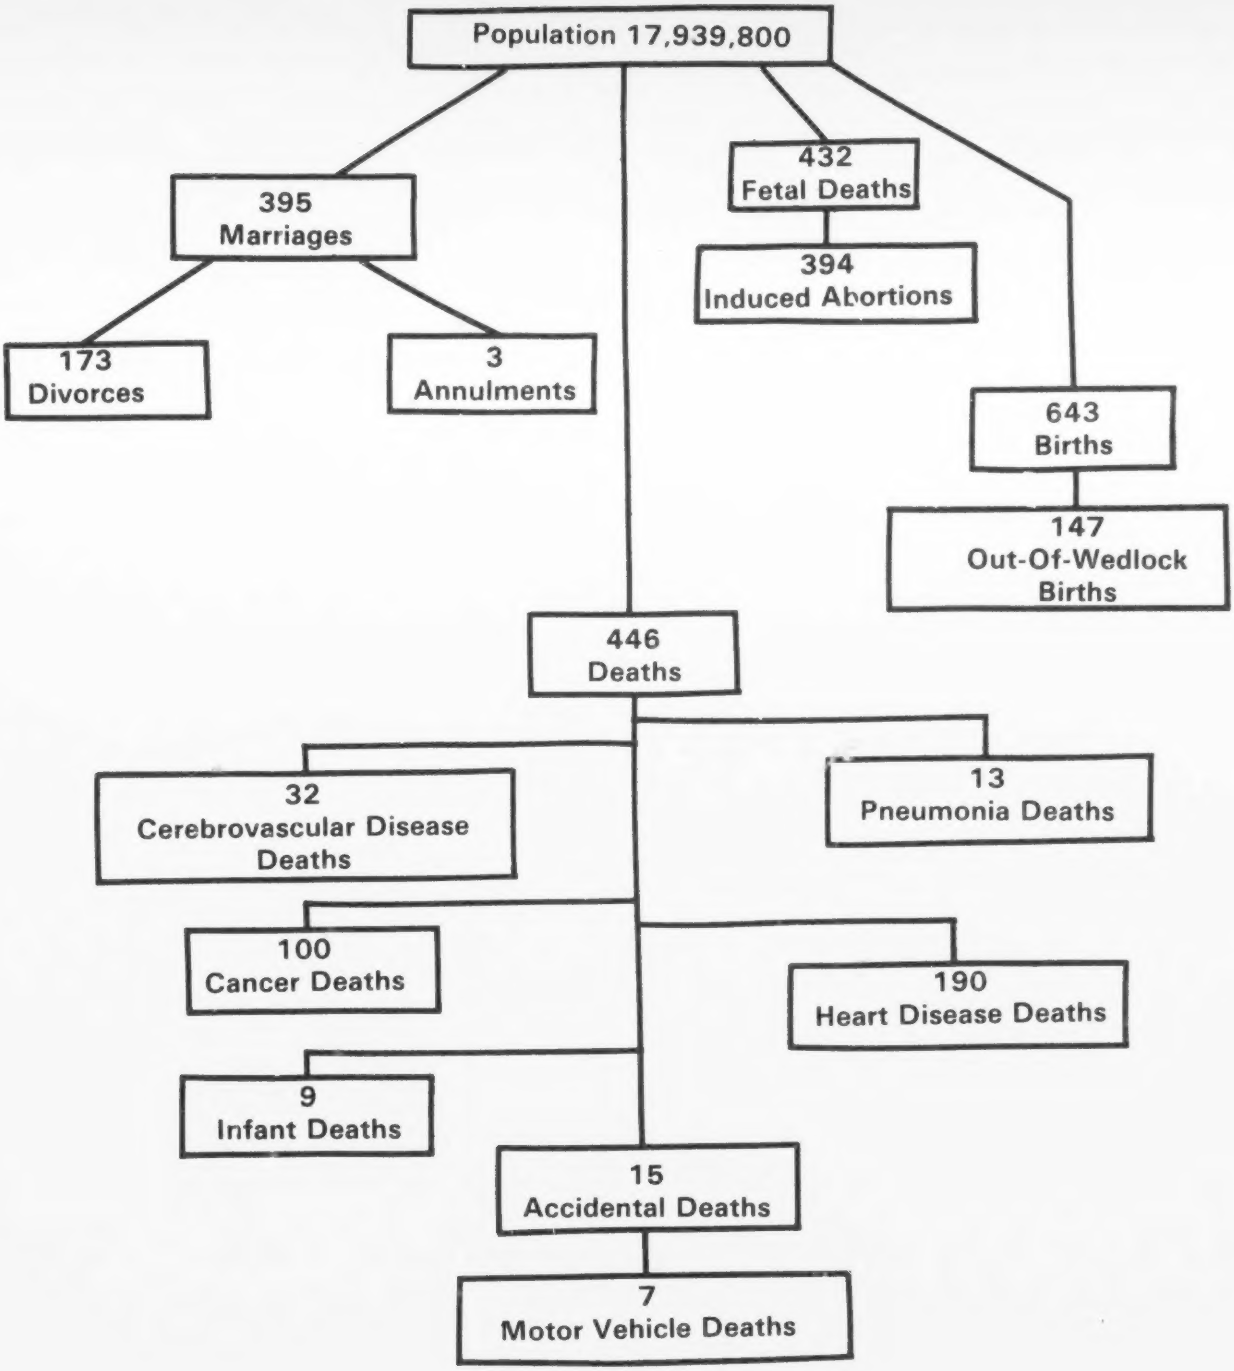
FIGURES, MAPS AND TABLES

The following symbols with their meanings are used in the figures and tables:

Symbol	Meaning
**	Not available/not tabulated
-	Quantity zero

FIGURE 1

EACH DAY DURING 1979, NEW YORK AVERAGED APPROXIMATELY:



Population 17,939,800
395 Marriages
173 Divorces
3 Annulments
432 Fetal Deaths
394 Induced Abortions
643 Births
147 Out-Of-Wedlock Births
446 Deaths
32 Cerebrovascular Disease Deaths
13 Pneumonia Deaths
100 Cancer Deaths
190 Heart Disease Deaths
9 Infant Deaths
15 Accidental Deaths
7 Motor Vehicle Deaths

FOOTNOTES FOR TABLE 29

1. The term "Upstate" means Rest of State (New York State exclusive of New York City).

2. All vital statistics rates are calculated using residence data. See TECHNICAL NOTES for definition of rates. Table 29 is a summary table of the vital statistics of New York State, 1977-1979. For a complete commentary on the data see, INTRODUCTION, TECHNICAL NOTES, HIGHLIGHTS, and the footnotes to Figures 2-6 and Tables 1-28.

3. A premature birth is defined as a live birth with birthweight under 2501 grams.

4. A birth with early prenatal care is defined as a live birth reporting prenatal care of the mother during the first trimester.

5. Marriage counts by place of occurrence are not available for villages and cities. For 1979 there were 1,833 marriages performed in New York City with licenses issued in Rest of State. The value 1,833 plus the figure for Rest of State (Upstate) given in Table 29 gives the figure for Rest of State which is quoted in Table 27. Monroe County dissolution of marriage counts are extremely low for 1978 due to the majority of their certificates being received after the marriage files were closed.

6. Dissolutions of marriage by place of occurrence are not available for villages and cities except New York City. The dissolutions of marriage are available by county of occurrence.

7. Percents and rates for all variables presented in the table exclude events in the "not stated" category.

8. The population estimates for the years 1977, 1978 and 1979 for New York State counties and places used in this table are revised estimates prepared by the Demography Unit of the Office of Biostatistics, New York State Health Department and are consistent with the U.S. Bureau of the Census estimates.
